

# Hardware Modeling [VU] (191.011) – WS25 –

## Synchronizers and Debouncers

Florian Huemer & Sebastian Wiedemann & Dylan Baumann

WS 2025/26

# Recall: MTBU Estimation

HWMod  
WS25

Sync. & Deb.

Recap

Synchronizers

Debouncing

- We can get a statistical estimate of the MTBU

$$MTBU = \frac{1}{\lambda_{in} \cdot f_{clk} \cdot T_W} \cdot e^{\frac{t_{res}}{\tau_C}}$$

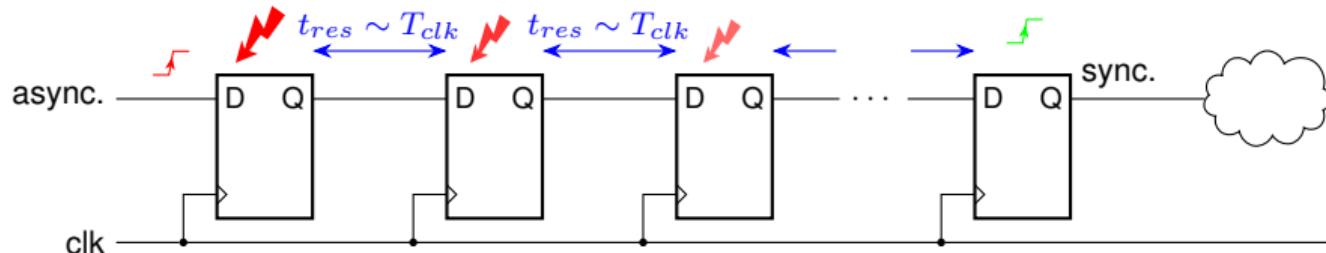

- Exponential dependence of MTBU on time to resolve  $t_{res}$ 
  - Increasing  $t_{res}$  is a mechanism to increase the MTBU
  - However: MTBU can never become infinite!
- Harnessed by *synchronizers*
  - Trade-off performance for a higher MTBU

# Waiting Synchronizers

HWMod  
WS25

Sync. & Deb.  
Recap  
Synchronizers  
VHDL  
Take Aways  
Debouncing

- Chain of flip-flops
  - Pass metastable output to next flip-flop in chain
  - No comb. logic between flip-flops  $\Rightarrow$  majority of clock period for resolution
  - Asynchronous input is “synchronized” to the clock
- Overall resolution time is the sum of the individual ones
  - $\Rightarrow$  Exponential increase in MTBU **per** flip-flop
- In practice often two flip-flops, three to be on the safe side
  - Trade-off between latency and MTBU

# VHDL Implementation

HWMod  
WS25

Sync. & Deb.  
Recap  
Synchronizers  
VHDL  
Take Aways  
Debouncing

```
1 library ieee;
2 use ieee.std_logic_1164.all;
3
4 entity synchronizer is
5   generic (
6     STAGES : natural;
7     RES_VAL : std_ulogic
8   );
9   port (
10     clk    : in std_ulogic;
11     res_n : in std_ulogic;
12     async : in std_ulogic;
13     sync  : out std_ulogic
14   );
15 end entity;
16
16 architecture arch of synchronizer is
17   signal ffs: std_ulogic_vector(0 to STAGES);
18 begin
19   process (clk, res_n) begin
20     if res_n = '0' then
21       ffs <= (others => RES_VAL);
22     elsif rising_edge(clk) then
23       ffs(0) <= async;
24       for i in 1 to STAGES loop
25         ffs(i) <= ffs(i-1);
26       end loop;
27     end if;
28   end process;
29   sync <= ffs(STAGES);
30 end architecture;
```

# Important Aspects

HWMod  
WS25

Sync. & Deb.  
Recap  
Synchronizers  
VHDL  
Take Aways  
Debouncing

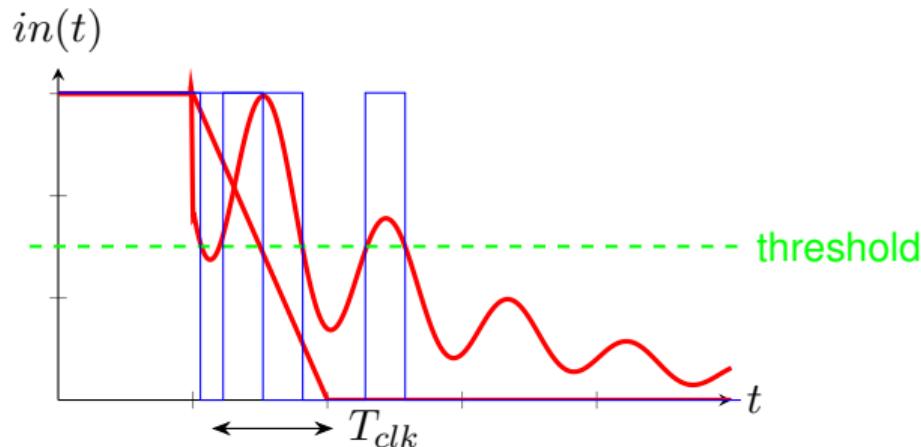

- MTBU can be made *arbitrarily* large by appropriate synchronizer
  - A synchronizer does **not** prevent metastability!
- A single flip-flop alone is not a synchronizer
- The MTBU is a statistical quantity
  - No guarantee for upset-freedom at any time

# Bouncing Inputs

HWMod  
WS25

Sync. & Deb.  
Recap  
Synchronizers  
Debouncing

- Asynchronous inputs are not the only problem at interfaces
- Some mechanical contacts may “bounce” due to their construction
  - For example: Mechanical buttons, switches
  - Instead of clean transition damped oscillation
  - Depending on clock frequency, takes multiple (hundred) clock cycles
- May upset input FFs or leads to unwanted transitions

# Counter Measures

HWMod  
WS25

Sync. & Deb.

Recap

Synchronizers

Debouncing

- Simply filter-out sequence of input transitions that is “too fast”
  - Analog (low pass) filtering
  - Digital filtering to check if output stabilizes
    - Use timer to wait (FSM)
    - Alternatives exist
  - Software-based debouncing

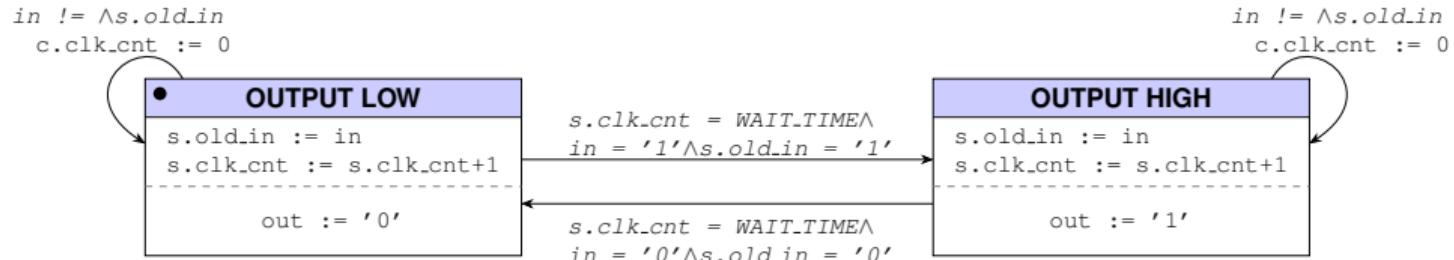

# Debouncer Implementation

HWMod  
WS25

Sync. & Deb.  
Recap  
Synchronizers  
Debouncing

## ■ Digital debouncing FSM

- Debouncer either outputs zero or high
- If the input changes, reset counter to count time since transition
- When input change is stable, change output
